임종우 (Jongwoo Lim)

C++ Template is

One of four polymorphisms in C++:

- Subtype polymorphism
 - > Runtime polymorphism
- Parametric polymorphism (C++ template !!)
 - Compile-time polymorphism
- Ad-hoc polymorphism
 - Overloading
- Coercion polymorphism
 - (Implicit or explicit) casting

Generic programming is a style of computer programming in which algorithms are written in terms of **to-be-specified-later** types that are then instantiated when needed for specific types provided as parameters. [wikipedia]

- C++ Standard Template Library (STL).
- Data containers such as matrix, vector, array, image, etc.
- Algorithms such as sorting, searching, hashing, etc.
- ...

```
// Suppose we want to sort an integer array.

void SelectionSort(int* array, int size) {
  for (int i = 0; i < size; ++i) {
    int min_idx = i;
    for (int j = i + 1; j < size; ++j) {
        if (array[min_idx] > array[j])
            min_idx = j;
    }
    // Swap array[i] and array[min_idx].
    int tmp = array[i];
    array[i] = array[min_idx];
    array[min_idx] = tmp;
}
```

```
// Suppose we want to sort an integer array.

void SelectionSort(int* array, int size) {
  for (int i = 0; i < size; ++i) {
    int min_idx = i;
    for (int j = i + 1; j < size; ++j) {
        if (array[min_idx] > array[j])
            min_idx = j;
    }
    // Swap array[i] and array[min_idx].
    int tmp = array[i];
    array[i] = array[min_idx];
    array[min_idx] = tmp;
}
```

```
// We also want to sort a double array.

void SelectionSort(double* array, int size) {
  for (int i = 0; i < size; ++i) {
    int min_idx = i;
    for (int j = i + 1; j < size; ++j) {
        if (array[min_idx] > array[j])
            min_idx = j;
    }
    double tmp = array[i];
    array[i] = array[min_idx];
    array[min_idx] = tmp;
}
```

```
// Suppose we want to sort an integer array.

void SelectionSort(int* array, int size) {
  for (int i = 0; i < size; ++i) {
    int min_idx = i;
    for (int j = i + 1; j < size; ++j) {
        if (array[min_idx] > array[j])
            min_idx = j;
    }
    // Swap array[i] and array[min_idx].
    int tmp = array[i];
    array[i] = array[min_idx];
    array[min_idx] = tmp;
}
```

```
// We also want to sort a double array.
void SelectionSort(double* array, int size) {
  for (int i = 0; i < size; ++i) {</pre>
    int min idx = i;
    for (int j = i + 1; j < size; ++j) {
      if (array[min idx] > array[j])
        min idx = j;
    double tmp = array[i];
    array[i] = array[min idx];
    array[min idx] = tmp;
// And also a string array.
void SelectionSort(string* array, int size) {
  for (int i = 0; i < size; ++i) {</pre>
    int min idx = i;
    for (int j = i + 1; j < size; ++j) {
      if (array[min idx] > array[j])
        min idx = j;
    string tmp = array[i];
    array[i] = array[min idx];
    array[min idx] = tmp;
```

• C++ template allows us to avoid this repeated codes.

```
// Suppose we want to sort an integer array.

template <typename T>
void SelectionSort(T* array, int size) {
   for (int i = 0; i < size; ++i) {
      int min_idx = i;
      for (int j = i + 1; j < size; ++j) {
        if (array[min_idx] > array[j])
            min_idx = j;
      }
   T tmp = array[min_idx];
   array[i] = array[min_idx];
   array[min_idx] = tmp;
   }
}
```

```
int main() {
  int array[] = { 2, 5, 3, 1, 4 };
  const int size = sizeof(array) / sizeof(int);
  SelectionSort<int>(array, size); // You may use SelectionSort(array, size);
  for (int i = 0; i < size; ++i) cout << " " << array[i];
  cout << endl;
  return 0;
}</pre>
```

HANYANG UNIVERSITY

```
template <typename T>
void Swap(T& a, T& b) {
   T tmp = a;
   a = b;
   b = tmp;
}

template <typename T>
void SelectionSort(T* array, int size) {
   for (int i = 0; i < size; ++i) {
      int min_idx = i;
      for (int j = i + 1; j < size; ++j) {
        if (array[min_idx] > array[j])
            min_idx = j;
      }
      Swap(array[i], array[min_idx]); // Clearly states the meaning of operation.
}
```

- Functions and classes can be templated.
- Template parameters can be typenames (= classes) or integers.

```
template <class First, class Second> // Same as <typename First, typename Second>.
struct Pair {
   First first;
   Second second;
};

template <typename T, int d> // d must be a constant integer.
void Reverse(T array[d]) { // Same as (T* array) - array size is not checked.
   for (int i = 0; i < d / 2; ++i) Swap(array[i], array[d - i - 1]);
}

int main() {
   int array[10] = { ... };
   int size = 10;
   Reverse<int, 10>(array); // OK.
   Reverse<int, size>(array); // Error.
   return 0;
}
```

```
template <class First, class Second>
struct Pair {
    First first;
    Second second;

    Pair(const First& f, const Second& s) : first(f), second(s) {}
};

template <class First, class Second>
Pair<First, Second> MakePair (const First& first, const Second& second) {
    return Pair<First, Second> (first, second);
}

int main() {
    Pair<int, int> p = MakePair(10, 10); // Equivalently MakePair<int, int>(10, 10);
    Pair<int, int> q = Pair<int, int>(20, 20);
    return 0;
}
```

```
template <typename T, int d>
class Vector {
public:
 typedef T DataType; // Access as Vector<T, d>::DataType.
 Vector() { for (int i = 0; i < d; ++i) vec [i] = T(); }
 Vector(const Vector& v) { for (int i = 0; i < d; ++i) vec [i] = v.vec [i]; }

 const T& operator[](int i) const { return vec [i]; }
 T& operator[](int i) { return vec [i]; }
 Vector operator+() const { return *this; }
 Vector operator-() const;
 T Sum() const;
 T Dot(const Vector& v) const;
private:
 T vec [d];
};
```

```
template <typename T, int d>
Vector<T, d> Vector<T, d>:: operator-() const {
 Vector<T, d> ret;
  for (int i = 0; i < d; ++i) ret.vec [i] = -vec [i];</pre>
  return ret;
template <typename T, int d>
T Vector<T, d>::Sum() const {
 T ret = T();
  for (int i = 0; i < d; ++i) ret += vec [i];</pre>
  return ret;
template <typename T, int d>
T Vector<T, d>::Dot(const Vector& v) const {
 T ret = T();
  for (int i = 0; i < d; ++i) ret += vec [i] * v.vec [i];</pre>
  return ret;
```

```
template <typename T, int d>
class Vector {
  public:
    // ....

    template <typename S>
    Vector<S, d> cast() const {
        Vector<S, d> ret;
        for (int i = 0; i < d; ++i) ret[i] = static_cast<S>(vec_[i]);
        return ret;
    }

    private:
    T vec_[d];
};
```

```
int main() {
   Vector<int, 3> v, w;
   Vector<int, 3>::DataType dot = v.Dot(-w);
   Vector<double, 3> x = v.cast<double>();
   cout << x.Sum();
   return 0;
}</pre>
```

```
int main() {
  Vector<int, 3> v;
  return 0;
}
```

```
template <>
class Vector<int, 3> {
public:
 typedef int DataType; // Access as Vector<T, d>::DataType.
 Vector() { for (int i = 0; i < 3; ++i) vec [i] = int(); }
 Vector(const Vector& v) { for (int i = 0; i < 3; ++i) vec_[i] = v.vec_[i]; }</pre>
 const int size() const { return d; }
 const int& operator[](int i) const { return vec [i]; }
 int& operator[](int i) { return vec [i]; }
 Vector operator+() const { return *this; }
 Vector operator-() const;
 int Sum() const;
 int Dot(const Vector& v) const;
private:
 <u>int</u> vec [3];
};
```

Inline Function

- Request the compiler to insert the function body in the place that the function is called.
 - The function body will not be included in the object file.
- Compilers are not obligated to respect this request.
- Member functions defined in the class definition are inlined.
- Inline function definitions are placed in header files.
- Pros/cons: eliminate function call overhead / code bloat.

```
inline void Swap(int& a, int& b) {
  int tmp = a;
  a = b;
  b = tmp;
}
```
